

FL-01 - AI Workflow Audit and Tool Setup

Workflow audit and setup evidence

1. Workflow Audit

Recurring task	Classification	Rationale
Webometrics ranking research and data analysis	Collaborate with AI	AI helps me explore analytical methods and interpret results, while I validate the data, methodology, and conclusions myself.
Analyzing anomalies and statistical results in Webometrics data	Collaborate with AI	AI helps identify patterns and possible explanations, but I verify whether the results are statistically and logically valid.
Writing and improving academic research papers	Collaborate with AI	AI helps with structure, wording, and idea exploration, while I verify research claims, evidence, and final conclusions.
Working on TensorFlow open-source issues and pull requests	Collaborate with AI	AI helps me inspect code and understand technical problems or review feedback, but I make and verify the actual changes myself.
Debugging TensorFlow build, Python, and dependency issues	Collaborate with AI	AI helps generate hypotheses from logs and errors, while I reproduce the issue and test proposed fixes in the actual environment.
Running tests and validating fixes before updating a pull request	Just me	I personally verify that the code builds, relevant tests pass, and the original problem is resolved before submitting changes.
Building and experimenting with Multi-Agent AI systems	Collaborate with AI	AI helps me compare architectures and implementation approaches, while I design, integrate, test, and evaluate the system.
Experimenting with RAG, CRAG, CAG, LAG, and Adaptive RAG	Collaborate with AI	AI helps compare retrieval approaches and troubleshoot experiments, while I evaluate their behavior and choose the appropriate architecture.
Writing backend and API code	Delegate to AI with review	AI can generate initial implementations and boilerplate, but I review, modify, test, and integrate the code myself.
Running repetitive model and system evaluations	Fully automate	Once evaluation criteria and metrics are defined, scripts can repeatedly run tests and collect results automatically.
Deciding whether code, research, or a project is ready to submit or release	Just me	Final approval requires my judgment because I am responsible for the correctness and quality of the submitted work.
Participating in the Huawei programming challenge	Collaborate with AI	AI can help me understand problems and explore possible approaches, while I evaluate and implement the final solution.
Designing technical architecture for AI and backend projects	Collaborate with AI	AI helps me compare designs and trade-offs, but I choose the architecture based on actual requirements and constraints.
Preparing technical documentation and README files	Delegate to AI with review	AI can help draft and organize documentation, but I verify that the final documentation accurately represents the implementation.

2. Three Target Tasks

1. Debugging a complex TensorFlow/software issue

Done well means: the root cause is identified, the fix is implemented, the relevant build or tests pass, and the original issue can no longer be reproduced.

2. Analyzing Webometrics ranking data and anomalies

Done well means: the analysis is reproducible, the statistical results are correct, suspicious patterns are supported by evidence, and the conclusions do not overstate what the data proves.

3. Designing and evaluating a Multi-Agent/RAG system

Done well means: the system architecture is clearly defined, the components work together correctly, retrieval or agent behavior is tested, and the chosen design is justified using measurable results.

3. Tool Setup and Evidence

ChatGPT: Account configured and in use.

Claude: Account configured. A dedicated Backend AI Engineering and Production Systems Collaboration project was created with custom instructions covering my background, preferred collaboration style, and current goals.

Anthropic Academy: Enrolled in AI Fluency: Framework & Foundations and completed the first module, Introduction to AI Fluency.

Evidence A - Configured Claude Project

I am an AI Engineer focused on Backend AI Engineering, machine learning, LLMs, RAG, multi-agent systems, APIs, and production AI systems.
Act as a technical collaborator. Help me reason through architecture, implementation, debugging, testing, evaluation, and deployment rather than simply giving me final answers.
Keep your responses clear, concise, technically precise, and practical. For technical problems, explain the reasoning behind important decisions and point out relevant trade-offs, reliability, security, and scalability considerations.
When generating code, prefer production-oriented solutions and explain important implementation decisions. Do not assume AI-generated code is correct; encourage testing and verification.
My current goal is to strengthen my Backend AI Engineering skills, improve how I collaborate with AI during development, and build reliable production-ready AI systems.

Got it. That's a solid working style for what we're doing — I'll push back on tradeoffs, ask about constraints before jumping to code, and flag where I'm uncertain or where you should verify/test rather than trust output blindly.

A few things that'll help me actually be useful as a collaborator rather than a code vending machine:

Context that matters per-task:

- Scale/constraints (latency SLOs, QPS, cost ceiling, team size) — architecture advice is meaningless without these
- What's already built vs. greenfield
- Language/stack preferences (Python + FastAPI? Go? something else?)
- Whether you want me to interrogate your design before you build it, or review something you've already built

How I'll default to working, unless you tell me otherwise:

- For architecture/design questions: I'll ask clarifying questions about scale, failure modes,

Evidence B - Anthropic Academy first module completed
